Introduction

The state of Idaho, Division of Idaho National Laboratory Oversight and Radiation Control (DEQ-INL) Environmental Surveillance Program (ESP) is conducted at locations on the INEEL, on the boundaries of the INEEL, and at distant locations to the INEEL in accordance with accepted monitoring procedures and management practices. This program is designed to provide the people of the state of Idaho with independently evaluated information about the impacts of the Department of Energy's (DOE) activities in Idaho.

The primary objective for DEQ-INL's ESP is to maintain an independent environmental monitoring and verification program designed to verify and supplement DOE's data and programs. This program is also used to provide the citizens of Idaho with information that has been independently evaluated to enable them to reach informed conclusions about DOE activities in Idaho and potential impacts to public health and the environment.

Results of the ESP are published using two distinct reporting formats: quarterly data reports and an annual ESP report. The annual ESP report is designed for a more broad audience and summarizes the results of the ESP for the previous four quarters. The annual report's primary emphasis is to focus on trends, ascertain the impacts of DOE operations on the environment, and confirm the validity of DOE monitoring programs. This quarterly report is designed to provide the mechanism to document the results of the ESP on a quarterly basis and provide detailed data to those who wish to "see the numbers." It is organized according to the media sampled and also provides a quality assurance assessment.

Air and Precipitation Monitoring Results

The ESP operated eight air monitoring stations on and near the INEEL as well as two monitoring stations distant from the INEEL during the first quarter, 2004 (**Figure 1**). These stations employed instrumentation for collecting airborne particulate matter (TSP and PM_{10}), gaseous radioiodine, precipitation, and water vapor for tritium analysis (**Table 1**). The Shoshone-Bannock Tribes operated an air monitoring station located at Fort Hall. Because this station uses identical instrumentation and sampling protocol, the DEQ-INL reports the data as an additional background site.

Starting in the first quarter of 2003, DEQ-INL designated the high-volume total suspended particulate (TSP) air sampler as the primary air sampler, thus replacing the aging PM_{10} samplers. There are currently three PM_{10} samplers collecting supplementary air data, along with radioiodine, at Fort Hall, Mud Lake, and Atomic City.

Weekly gross alpha and gross beta radioactivity results for filters from the TSP samplers are presented in **Appendix A** and summarized in **Table 2**. Gross alpha and gross beta radioactivity concentrations reported from the particulate samples were within the range of expected values for naturally occurring radioactivity observed historically. Monthly averages for gross beta concentrations for each location are presented in **Figures 2** through **12**. The monthly averages are consistent with background values. Fluctuations in the monthly values are typical of observed seasonal variations.

Weekly gross alpha and gross beta radioactivity results for the PM_{10} particulate air filters are presented in **Appendix B** and summarized in **Table 3**. Gross alpha and gross beta radioactivity concentrations reported from the particulate samples were within the range of expected values for naturally occurring radioactivity.

Composites of filters collected using TSP and PM_{10} samplers during the course of a calendar quarter are analyzed using gamma spectroscopy. Typically, gamma spectroscopy results are only reported when exceeding a minimum detectable activity (MDA) or minimum detectable concentration (MDC). Gamma spectroscopy results for the first quarter of 2004 for TSP filters are presented in **Table 4** and gamma spectroscopy results for PM_{10} filters are presented in **Table 5**. The only reported gamma-emitting radionuclide detected was beryllium-7, a naturally occurring, cosmogenic radionuclide.

Annual composites of filters collected using TSP and PM₁₀ samplers are also analyzed using radiochemical separation techniques. The samples are analyzed for strontium-90, plutonium-238, plutonium-239/240, and americium-241. The results of radiochemical separation can be found in **Table 6** and **Table 7**. Results indicate activity concentrations exceeding the MDC min some instances, but well below the DEQ-INL action level for the specific radionuclides. Measurable quantities of these radionuclides are expected in the environment due to historic above ground testing of nuclear weapons.

Sample media, which collects gaseous radioiodine in air, were analyzed from 11 sample locations. No radioactive isotopes of iodine, specifically iodine-131, were detected on the weekly charcoal cartridges.

Atmospheric moisture samples were collected at 11 locations and analyzed for tritium. Atmospheric tritium concentrations were determined using the amount of tritium measured in the quantity of atmospheric moisture collected per volume of air sampled. Reported values are the result of either a single sample or a weighted mean when more than one atmospheric moisture sample was collected during the calendar quarter. No atmospheric tritium was measured at onsite or offsite locations during the first quarter of 2004. Average atmospheric tritium concentrations are presented in **Table 8**.

Precipitation samples were collected at six monitoring locations during the first quarter of 2004. Precipitation samples are analyzed for tritium and gamma-emitting radionuclides. Tritium and gamma-emitting radionuclides were below minimum detectable concentration in precipitation collected during the first quarter of 2004. Tritium and cesium-137 analysis results are presented in **Table 9**. Reported values are either the result of a single sample or a weighted mean when more than one precipitation sample was collected during the calendar quarter.

Environmental Radiation Monitoring Results

The ESP operated 14 environmental radiation stations during the first quarter of 2004 (**Figure 1**). Each of these stations is instrumented with an electret ionization chamber (EIC), and 11 of the stations also have high-pressure ion chambers (HPIC) (**Table 10**). The Shoshone-Bannock Tribes operate an environmental radiation station at Fort Hall. The DEQ-INL reports these results.

HPICs are instruments capable of real-time measurements, and therefore can detect small changes in gamma radiation levels over time. Since HPICs offer real-time gamma radiation measurement and data acquisition, DEQ-INL collects this information electronically and provides graphed data via the world wide web at www.idahoop.org. Contrastly, EICs are a passive integrating system that provides a cumulative measure of environmental gamma radiation exposure. DEQ-INL compared the exposure rates measured by EICs and HPICs and observed that the data correlated very well from both measurement methods (A Comparison of Three Methods for Measuring Environmental Radiation, Moser, Kristi, Idaho State University, M.S.Thesis, 2002). Each system is used by DEQ-INL to measure gamma radiation for various radiological monitoring objectives. EICs offer an inexpensive methodology to measure gamma radiation over a wide area, particularly in regions which do not have a power source. EICs can also provide valuable gamma radiation data in the event of an emergency. It is because of this reason that EICs are also deployed at 78 locations by DEQ-INL in a widespread network around the INEEL measuring general background radiation. This information is tabulated in Appendix C.

Table 11 lists the average radiation exposure rates measured by the HPICs for the quarter. Exposure rates were within the expected range of values for historical background radiation.

Table 12 lists the EIC monitoring results for first quarter, 2004. Because of the inaccessibility of three sites due to deep snow (Base of Howe, Rover, and Big Southern Butte), EICs were not collected from these locations in the fourth quarter of 2003. Data retrieved from these sites when weather conditions allowed access, were added to their respective data sets collected in the first quarter of 2004.

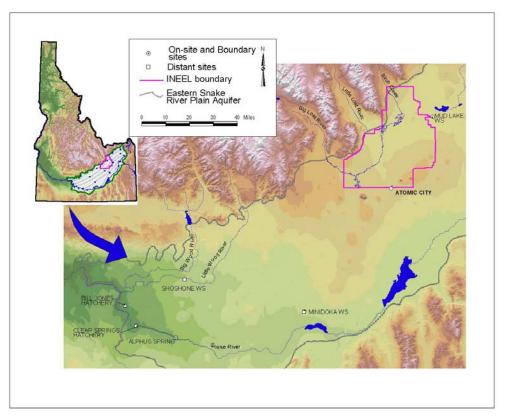

Figure 14. Water monitoring locations.

Water Monitoring & Verification Results

Water Monitoring Sampling Program

Seven water monitoring locations were sampled during the first quarter of 2004, two sites near the INEEL boundary and five sites offsite and distant from the INEEL, with duplicate samples collected at one site. Water monitoring sites are shown in **Figure 14** and gross alpha, gross beta, and gamma spectroscopy results are presented in **Table 13**.

No samples returned detectable gross alpha radioactivity this quarter. Occasional detections for gross alpha radioactivity are expected for Snake River Plain Aquifer sites due to naturally occurring uranium and thorium isotopes in the groundwater.

Gross beta radioactivity was detected in samples from two distant sites. Detectable concentrations ranged from 2.6 ± 1.1 to 4.2 ± 1.2 pCi/L. The highest concentration was observed for a sample from the distant location, Alpheus Spring. The typical background range for gross beta radioactivity for the Snake River Plain Aquifer is 0 to 8 pCi/L. Gross beta analyses are conducted as a screening tool for beta-emitting radionuclides that were released due to INEEL operations, such as strontium-90 and technetium-99. Samples from selected onsite locations are sampled for these radionuclides during the second and fourth calendar quarters. No man-made, gamma-emitting radionuclides were detected.

Tritium was not detected in samples collected this quarter using the standard analysis method. Results for tritium analyses are presented in **Table 14**.

Water samples not exceeding the tritium MDC using the standard methods (160 pCi/L) are routinely reanalyzed using an electrolytic enrichment method with a much lower MDC (10 to 14 pCi/L). These samples are all presented in **Table 15**. Values are consistent with typical background levels of tritium of 0 to 40 pCi/L and significantly below the drinking water EPA limit of 20,000 pCi/L.

No samples were collected for trace metals, common ions, or nutrient analyses this quarter.

Water Verification Sampling Program

Water verification sampling sites are shown on **Figure 15**. During the first quarter of 2004, the DEQ-INL sampled four wells on the INEEL. Radiological results are shown in **Tables 16-21** and the non-radiological data are in **Tables 22-25**. These data are collected primarily to compare results with the co-sampling agencies at the INEEL (i.e., BBWI and the monitoring groups at ANL-W and NRF), so only a brief synopsis follows. Results of the comparisons are reported in the DEQ-INL annual report.

² Data reflects the average of an actual sample result and the result of a corresponding laboratory split, recount, re-distillation, or re-evaporation.

² Data reflects the average of an actual sample result and the result of a corresponding laboratory split, recount, re-distillation, or re-evaporation.

None of the samples collected this quarter contained detectable levels of americium-241, plutonium isotopes, or strontium-90. Tritium was detected in areas of known INEEL contamination, M3S, TRA-7, and TRA-8, at concentrations below the drinking water standard of 20,000 pCi/L. Technetium-99 was also detected in areas of known contamination at M3S and M1S.

Carbon tetrachloride and trichloroethene were detected in well M3S, near the RWMC. These contaminants have migrated down to the aquifer from wastes buried at that facility. The vapors are being pumped from the subsurface and remediated with a treatment system. Elevated chromium concentrations were reported in samples from wells near the RWMC and TRA; concentrations at TRA-7 exceeded the drinking water standard of $100~\mu g/L$.

Terrestrial Monitoring Results

The ESP conducts terrestrial (soil and milk) sampling as an extension of air pathway surveillance. Terrestrial monitoring and verification provides an indication as to the long-term deposition and migration of contaminants in the environment, and independent verification of DOE's analytical measurement of terrestrial variables, respectively.

Results for analyses of milk samples, which are collected monthly, are presented in **Table 26**. Naturally occurring potassium-40 was detected in all samples within the expected range. Iodine-131, a man-made radionuclide, was not detected.

DEQ-INL monitors long-term radiological conditions using measurement devices capable of identifying and measuring quantities of gamma-emitting radionuclides in soil. Monitoring concentrations of gamma-emitting radionuclides in surface soil provides insight to the transport, deposition, and accumulation of

radioactive material in the environment as a result of INEEL operations and the historic atmospheric testing of nuclear weapons.

No soil samples were collected during the first quarter of 2004.

Quality Assurance

This section summarizes the results of the quality assurance (QA) assessment of the data collected for the first calendar quarter of 2004 for the DEQ-INL's ESP. It also summarizes the quality control (QC) samples (spikes, blanks, and duplicates) submitted to the Idaho Bureau of Laboratories-Boise (IBL) for nonradiological analyses and to Idaho State University's Environmental Monitoring Laboratory (EML) for radiological analyses during the quarter. All analyses and QC measures in the analytical laboratories are performed in accordance with approved written procedures maintained by each respective analytical laboratory. Sample collection is performed in accordance with written procedures maintained by the DEQ-INL.

The measurement of any physical quantity is subject to uncertainty from errors that may be introduced during sample collection, measurement, calibration, and the reading and reporting of results. While the sum of these inaccuracies cannot be quantified for each analytical result, a quality assurance program can evaluate the overall quality of a data set and possibly identify and address errors or inaccuracies.

Analytical results for blanks, duplicates, and spikes are used to assess the precision, accuracy, and representativeness of results from analyzing laboratories. During the first quarter of 2004, the DEQ-INL submitted 54 QC samples for various radiological and nonradiological analyses (**Table 27**).

Blank Samples

Blank samples consist of matrices that have negligible, acceptably low, or unmeasurable amounts of the analyte(s) of interest in them. They are designed to determine if analyses will provide a "zero" result when no contaminant is expected to be present or an acceptable measure of "background," and therefore monitor any bias that may have been introduced during sample collection, storage, shipment, and analysis. Blank sample results submitted for gross alpha and gross beta screening in air for the first quarter of 2004 are presented in **Table 28** and graphically depicted in **Figures 16** and **17** over the first quarter. Blank sample results for select gamma emitters in air from composited air filters are presented in **Table 29**. Blank results for radiochemical analysis of particulate air samples are found in **Table 30**. Data for blank analyses used to assess data quality for tritium in water vapor in air are presented in **Table 31**. Additionally, no blank analyses were conducted for metals, common ion, and nutrients in ground and surface water for the first quarter of 2004. Blank analyses results for cesium-137, potassium-40, tritium, enriched tritium, gross alpha, and gross beta in ground and surface water media are presented in **Table 32**.

No anomalies were observed from the assessment of blank samples submitted to the analytical laboratories for the first quarter of 2004.

Duplicate Samples

Duplicate samples are collected in a manner such that the samples are thought to be essentially identical in composition and are used to assess analytical precision. The difference between the original sample and the duplicate sample is expressed as a relative percent difference (RPD) and is used to measure a laboratory's ability to reproduce consistent results. For radiological analyses, the standard deviation of the differences can be used as an indicator of the overall precision of the data set. Duplicate results for ground and surface water are presented in **Table 33** for radiological analyses.

No anomalies were observed from the assessment of duplicate samples submitted to the analytical laboratories for the first quarter of 2004.

Spiked Samples

Spiked samples are samples to which known concentrations of specific analytes have been added. One indicator of agreement is the difference between the known concentration in the sample and the measured concentration, expressed as percent recovery (%R). This quantity is calculated to assess the bias a laboratory may have in accurately measuring analytes in a particular sample. No field matrices were spiked to assess the influence of the sample media on laboratory performance. Additionally, no spiked samples were submitted for nonradiological or radiological analysis during the first quarter of 2004.

Once per quarter, DEQ-INL irradiates a number of electret ionization chambers (EIC) to verify EIC response. Irradiations of EICs are conducted in a repeatable geometry to a known exposure of 30 mR and a "blind" exposure ranging from 20 to 50 mR. EIC responses are compared directly with the exposure received from the NIST traceable cesium-137 source provided by Idaho State University. EIC response is considered acceptable if each irradiated EIC agrees within 25 percent. The irradiation results for first quarter 2004 are presented in **Table 34.**

No anomalies were observed from the assessment of measuring known irradiated quantities to EICs for the first quarter of 2004.

Analytical QA/QC Assessment During First Quarter, 2004

No issues involving sample chain of custody, sample holding times, and data usability and completeness were observed during the first quarter of 2004. Data reports issued by the contracting laboratories conformed to the requirements of DEQ-INL. No transcription errors were noted for first quarter 2004 data.

Preventative Maintenance and Equipment Reliability

All equipment was calibrated and checked according to pre-described periodicity. Service reliability for air sampling equipment for the first quarter is summarized in **Table 35**. Air sampling equipment requiring repair included:

- The intermediate-flow PM₁₀ sampler pump at the Fort Hall monitoring station (pump replaced repair completed).
- The tritium sampler pump at the Fort Hall monitoring station (pump replaced repair completed).
- The hour meter, connected to the tritium sampler pump, at the Atomic City monitoring station (hour meter replaced repair completed).
- The low-volume air sampler (radioiodine sampler pump) at the Van Buren monitoring station (pump replaced repair completed).
- The tritium sampler pump at the Monteview monitoring station (not repaired low-volume air samplers at these locations are being used to sample both radioiodine and tritium).
- The tritium sampler pump at the Van Buren monitoring station (not repaired low-volume air samplers at these locations are being used to sample both radioiodine and tritium).
- The low-volume air sampler (radioiodine sampler) rotameter at the Howe monitoring station (rotameter replaced repair completed).

Additionally, six new low-volume air samplers were received during the quarter. These samplers will be used as back-up samplers to the samplers currently deployed.

Resolution of Past Analytical Issues

During the fourth quarter of 2003, 12 samples analyzed for technecium-99 by the EML using the EmporeTM disk method exceeded the MDC in all 12 samples, including those for wells that had no prior history of technetium-99 contamination. The laboratory hypothesizes that the problem was caused by an interaction between minerals in the sample water and the liquid scintillation fluid currently used (ScintiVerseTM). Ongoing experiments indicate that Packard Ultima Gold XR does not exhibit the interference and it has been used for subsequent analyses. The settings for the Wallac liquid scintillation counter have been tuned to this cocktail and a qualitative inspection of the sample spectrum has been incorporated into the analysis procedure. The Packard Tri-Carb liquid scintillation counter was similarly tuned for the technecium-99 analysis. DEQ-INL concurs with this resolution.

Conclusion

All data collected for the first calendar quarter of 2004 has been assigned the applicable qualifiers to designate the appropriate use of the data In addition, all data has been verified and deemed complete, meeting the requirements and data quality objectives established by DEQ-INL.

Table 27. Summary of the number and distribution of analyses performed for the DEQ-INL ESP for first quarter, 2004.

Media Type	Analyte	Test Analyses	Blank Analyses	Duplicate Analyses	Spike Analyses		
Air - Gaseous and Particulate	Gross alpha	143	13	0	0		
	Gross beta	143	13	0	0		
	Gamma emitters	11	1	0	0		
	Radiochemical	11	1	0	0		
	lodine-131	13	0	0	0

Air- Precipitation	Tritium	6	0	0	0		
	Gamma emitters	6	0	0	0		
Groundwater	Gross alpha	11	1	1	0		
& Surface Water	Gross beta	11	1	1	0		
	Gamma emitters	11	1	1	0		
	Tritium	11	1	1	0		
	Enriched tritium	7	1	1	0		
	Technicium-99	2	0	0	0		
	Radiochemical	4	0	0	0		
	Metals	4	0	0	0		
	Common Ions	4	0	0	0		
	Nutrients	4	0	0	0		
	Volatile Organics	2	0	0	0		
Terrestrial - Milk	Gamma emitters	21	0	0	0		
Terrestrial - Soil	Gamma emitters	0	0	0	0		
Radiation - EICs	Ambient Gamma Radiation	93	4	0	8		
Total Analyses by Type		540	41	5	8		
Total of Quality Control Analy (Blanks, Duplicates, & Spikes					54		
ercentage of Quality Control Analyses Collected Total # QC Analyses/Total Analyses performed)							

Collecting quality control samples at a rate of approximately 5 to 10% of the total number of samples collected for the year is deemed appropriate for the ESP.

Table 28. Blank analysis results for gross alpha and beta in particulate air (TSP) for the first quarter, 2004. Concentrations¹ and associated uncertainties (2 SD) are expressed in 1 x 10⁻³ pCi/m³.

¹ NC = sample not collected at this location; CP = sample collected using the PM₁₀ sampler at this location.
² No mechanical repair was required for the Mud Lake PM₁₀ sampler pump. Speculation as to the loss of service was most likely due to a local loss of electrical power.

Operated by Shoshone-Bannock Tribes.
